### Epochs of AD Research

Epoch	Years	Key Event	Principles
Clinical Observation	1906-1960s	<u>Alzheimer:</u> links dementia to plaques & tangles	<ul style="list-style-type: none"> <li>• “Strange Disease of the Cerebral Cortex”</li> <li>• Pre-senile dementia</li> </ul>
Human Pathology	1960s-1990s	<u>Blessed et al:</u> Plaques & tangles are common in senile dementia	<ul style="list-style-type: none"> <li>• Collapse of the age dichotomy</li> <li>• Convergence of Alzheimer’s disease (pathology) and dementia of the Alzheimer type (clinical)</li> </ul>
Animal models	1980s-current	<u>Glennner et al:</u> Amyloid is sequenced	<ul style="list-style-type: none"> <li>• Amyloid biology is clarified</li> <li>• Genetics of autosomal dominant AD</li> </ul>
Human Biomarkers	2000s-current	<u>Klunk et al:</u> <i>in vivo</i> amyloid imaging	<ul style="list-style-type: none"> <li>• Disease process has long silent period</li> </ul>

---

### Diagnostic schemes have evolved with the research

- DSM (1952) – Organic Brain Syndrome
- DSM-III (1980) Primary Degenerative Dementia
  - Senile vs. Presenile
- NINDS-ADRDA (1984) – Possible/Probable/Definite
- DSM-IV (1987) – Dementia of the Alzheimer Type
- NIA-AA (2011) – Separated pathology from dementia
  - Preclinical AD can now be defined
- DSM 5 (2013) – Major Neurocognitive Disorder
- Revised NIA-AA (2018) – Separate staging of pathology and clinical features (A-T-N)

---

---

---

### Traditional view

Amyloid plaque damages brain cells

Alzheimer cells

healthy cells

http://filippies.com/adflipoff/wp-content/plugins/RSSPoster\_PRO/cache/sccdd\_cells.jpg

---

---

---

---

---

---

---

---

---

---

### Newer view:

Amyloid damage begins *before* the plaque forms

http://www.sciencenews.org/pictures/031211/alzheimers\_illustration\_zoom.jpg

---

---

---

---

---

---

---

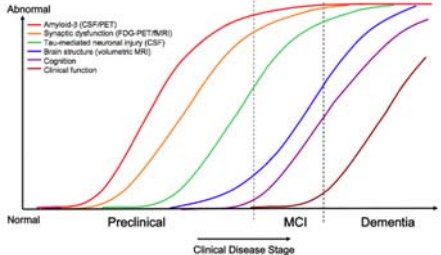

---

---

---

### Preclinical Alzheimer disease

Amyloid and tau are temporally dissociated

Abnormal

- Amyloid-β (CSF/PET)
- Synaptic dysfunction (FDG-PET/MRI)
- Tau-mediated neuronal injury (CSF)
- Brain structure (volumetric MRI)
- Cognition
- Clinical function

Normal Preclinical MCI Dementia

Clinical Disease Stage

Sperling et al. Alzheimer's and Dementia, 2011;7:280-92.

## Detecting the biomarkers

---

---

---

---

---

---

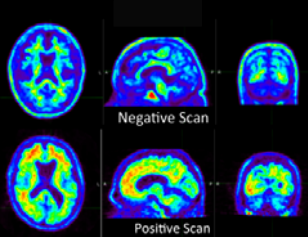

---

---

### Amyloid PET

*Evidence for A $\beta$  pathophysiology*

- Detects amyloid plaques
- In early onset autosomal dominant AD, becomes positive decades before symptoms
- FDA approved
- Essentially no insurance coverage
- Meaningful effect on therapeutic decision making (IDEAS study)

The image displays two rows of PET scans. The top row, labeled 'Negative Scan', shows three brain slices with low levels of amyloid plaque, appearing mostly in blue and green. The bottom row, labeled 'Positive Scan', shows three brain slices with high levels of amyloid plaque, appearing in yellow, orange, and red. The scans are arranged in a 2x3 grid.

---

---

---

---

---

---

---

---

### Next steps

*Tau imaging*

The image shows three PET scans labeled 'Healthy control', 'MCI', and 'AD'. A color scale on the left indicates SUVR values from 0 (blue) to 3 (red). The 'Healthy control' scan shows low SUVR (mostly blue/green). The 'MCI' scan shows moderate SUVR (yellow/green). The 'AD' scan shows high SUVR (yellow/red). The scans are arranged horizontally.

---

---

---

---

---

---

---

---

### FDG-PET in AD

*Evidence of neuronal injury*

- Measures brain glucose metabolism
- FDA approved
- Very limited insurance coverage

**NORMAL**      **ALZHEIMER'S**

---

---

---

---

---

---

---

---

### Hippocampus Atrophy in AD

*Evidence of neuronal injury*

HP  
ERC

Diara R, et al Front Aging Neurosci. 2013;5:47

---

---

---

---

---

---

---

---

### What about genetics?

*Alzheimer genetics and amyloid*

- Early onset AD is caused by autosomal dominant, highly penetrant, deterministic mutations
  - All result in amyloid overproduction
  - These mutations are found in less than 1% of all AD cases
    - Only 50% of Early onset, autosomal dominant AD
  - Onset in these cases is almost always before age 50
- Late onset AD has been linked to more than 30 genes
  - Most of these affect amyloid removal, not production
  - None contribute more than 20% of the variance
    - Most contribute <3% of the variance
- Thus, no genetic test can reliably predict most AD

---

---

---

---

---

---

---

---

### Common “software” issues that mimic AD

- Depression/Anxiety
- Sleep issues including OSA
- Pain/Pain medications

- These all tend to have bigger mismatches between
  - Complaints and scores
  - Complaints and daily function

## Alzheimer Therapeutics in 2018

**LEO PHARMACEUTICALS**  
*Knowledge that will change your world*

---

---

---

---

---

---

---

---

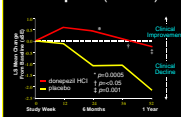

---

---

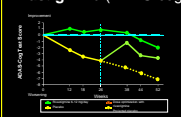

### Cholinesterase Inhibitors

*Stabilize cognition over one year*

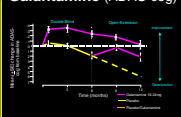

**Donepezil (MMSE)**

**Rivastigmine (ADAS-cog)**

**Galantamine (ADAS-cog)**

Among people with mild and moderate AD, treatment with any of the three drugs results in reduced loss of ability over one year.

### Delay to Nursing Home Placement (NHP)

- Eight (of 9) published studies report delayed admission or reduced risk for NHP with drug treatment
  - Risk is lowered by 28% at 1 year, 21% at 2 years, but there is no difference after three years<sup>2</sup>
- Caregiver support also delays NHP, but does not add to the medicine's effects<sup>3</sup>
- All delayed NHP results probably reflect access to high quality dementia care and good family support

### Removing brain amyloid in AD dementia

Good News/Bad News

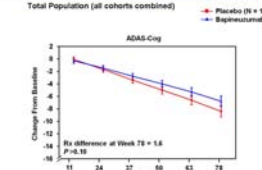

**Treated**

**Placebo**

Anti- $\alpha\beta$  antibodies successfully removed  $\text{A}\beta$  from the brain

**Clinical Efficacy: Linear-in-Time Model**  
 MTT Population Using RM Model With Linearity Assumption

Total Population (all cohorts combined)

Change From Baseline

Week

ADAS-Cog

Placebo (n = 107)

Bapineuzumab (n = 123)

Rx difference at Week 78 = 5.6  
 P=0.10

No clinical effectiveness  
 Substantial adverse effects

Rinne et al, *Lancet Neurology* 2010;9:363-72

### Lifestyle approaches to cognition and AD

Target	Observational Studies	Controlled Trials
Diet*	↓ Risk with high antioxidant and PUFA intake	Improved cognition and lower AD risk
Cognitive activity	↓ Dementia risk with high education and more cognitive engagement	Improved cognition and less decline
Physical* activity	↓ AD risk with high activity in mid & late life	Improved cognition with exercise

---

---

---

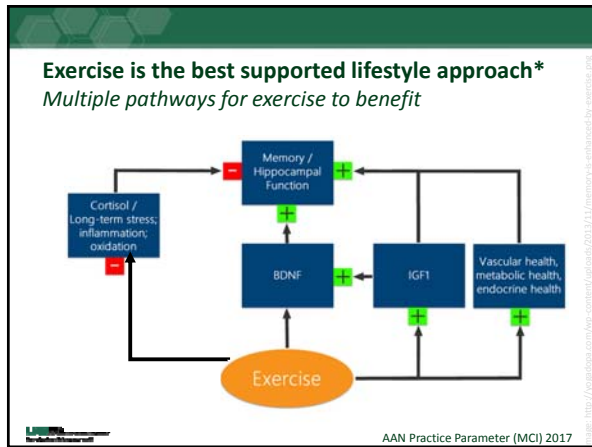

---

---

---

---

---

---

---

---

---

---

---

---

- ### Summary
- Alzheimer’s disease definitions have been a moving target based on research successes (and failures)
  - Current treatments are meaningful, but not sufficient to fully address patient or public needs
  - Future treatments will likely need to start very early in the course
    - Treat amyloidosis and tauopathy to prevent neurodegeneration.
    - Biologics can provide proof of concept, but cost will likely limit long-term wide-ranging utility
  - Risk-lowering lifestyle approaches offer promise
